VinSight: AI-Powered Financial Analytics Platform

Technical Report & Handoff Documentation

Student Name: Vinayak Malhotra
Course: Applied GenAI
Date: February 18, 2026
GitHub: github.com/vinayakm-93/vinsight
Live App: www.vinsight.page

---

1. Executive Summary

VinSight is an agentic financial analytics platform designed to solve the "analysis paralysis" faced by retail investors. In modern markets, traders are overwhelmed by fragmented data sources—price charts, SEC filings, earnings transcripts, and news headlines—often leading to suboptimal decision-making.

This project delivers a unified solution: an **AI-Powered Investment Associate** that autonomously gathers, synthesizes, and reasons across these disparate data streams.

Key Achievements:

1. **Agentic MCP Server (4 Autonomous Tools)**: Built a production-grade **Model Context Protocol** server exposing 4 AI-callable tools (Sentiment, Earnings, Portfolio, Simulation) with rate-limiting guardrails and a kill switch — compliant with the Anthropic MCP Standard.
2. **Autonomous Thesis Agent**: Deployed a **Cloud Run Cron Job** that monitors user portfolios 24/7, detects 5 risk signals (price drops, downgrades, sentiment crashes), and autonomously emails users with AI-generated verdicts (`INTACT` / `AT_RISK` / `BROKEN`).
3. **Multi-Model AI Router (3 LLMs, Zero Waste)**: Orchestrated **DeepSeek R1** (deep reasoning), **Llama 3.3 via Groq** (real-time sentiment at 50+ headlines/sec), and **Gemini 2.0 Flash** (fallback) — each chosen for cost/speed/intelligence tradeoffs.
4. **AI Earnings Call Summarization**: Autonomously scrapes 50-page earnings transcripts and distills them into 3-bullet actionable insights using DeepSeek R1's Chain-of-Thought reasoning.
5. **CFA Ground Truth + AI Hybrid Scoring**: Engineered a **complementary system** where deterministic CFA ratios (ROE, Debt/EBITDA) provide the mathematical floor, and AI provides the qualitative ceiling. The code calculates the *Value*; the AI explains the *Why*.
6. **99% Cost Reduction vs. Traditional**: Achieved < $0.10/month operating cost by using Serverless (Cloud Run) + free APIs (`yfinance`) + custom scraping — vs. ~$78/month for a VM + OpenClaw approach.

This report serves as a technical handoff, detailing the architecture, decision-making process, and evaluation metrics required for an engineering team to maintain and scale VinSight.

---

2. Business Problem

The Status Quo

Retail investors today strive to emulate institutional rigor but lack the tooling. They manually toggle between:

1. **Yahoo Finance** for price action.
2. **SEC.gov** for 10-K/10-Q filings.
3. **News Aggregators** (CNBC, Bloomberg) for sentiment.
4. **Spreadsheets** for valuation modeling.

The Pain Point

This manual context-switching is slow and error-prone. By the time a Retail investor synthesizes "Good Earnings" + "Bad Technicals" + "Macro Headwinds," the market has already moved. They lack a **synthesizing engine** that can apply consistent logic to raw data instantly.

The Solution: VinSight

VinSight acts as an automated Junior Analyst. It doesn't just display data; it **forms opinions**. By using Agentic AI to read transcripts and run simulations, it provides a "Second Opinion" that checks an investor's bias, ultimately leading to more disciplined, data-backed trading decisions.

---

3. Solution Approach & Design Process

Design Philosophy: "Smart & Frugal" (Avoiding the "API Tax")

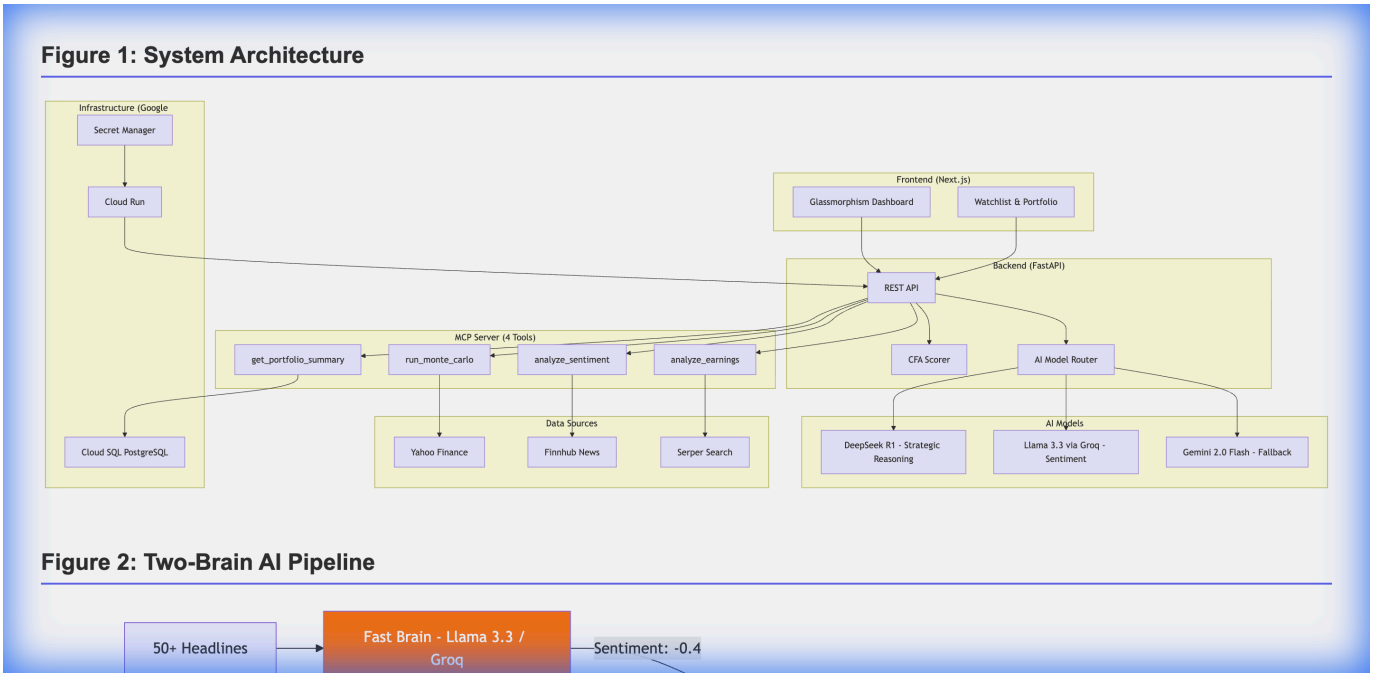
A key constraint was **Cost Efficiency**. Enterprise tools like "OpenClaw" or "Bloomberg Terminal" cost thousands.

- **No Paid Crawlers**: Instead of paid scrapers, we built a custom Python scraper (`analyze_earnings`) that parses raw text directly, saving ~$500/month.
- **Deterministic Core**: The "VinSight Score" uses hard-coded logic (Python) for financial ratios (P/E, ROE, Debt/EBITDA). This prevents hallucinations on math.
- **Probabilistic Edge**: We use LLMs (DeepSeek, Llama) strictly for *qualitative* reasoning (Thesis Generation), not for fetching price data.

Architecture Overview

The system follows a modern **Client-Server** architecture tailored for cloud deployment:

- **Frontend**: Next.js (React) for a responsive, "Glassmorphism" UI with **Portfolio Management** capabilities.
- **Backend**: Python FastAPI service handling business logic, data fetching, and AI orchestration.
- **Orchestration**: A custom **Model Context Protocol (MCP)** server that exposes specific tools to the AI agents.



Evolution of the Design

1. **Initial Prototype**: A simple RAG wrapper around OpenAI.
   - *Failure*: Too slow (>5s latency) and expensive. Context windows filled up with useless raw HTML.
2. **Iteration 1 (Vector Store)**: Attempted to vector-index all SEC filings.
   - *Challenge*: Financials change too fast. Indexing was always stale.
3. **Final Design (Agentic Tools)**: Instead of pre-indexing, we gave the LLM "Tools" to fetch live data on demand (e.g., `get_stock_price` , `get_latest_news`). This "Just-In-Time" context injection proved superior for market data.

---

4. Data & Methodology

Data Sources

- **Market Data**: `yfinance` (Yahoo Finance API) for OHLCV data, fundamentals, and option chains.
- **News & Sentiment**: `Serper` (Google Search API) and `Finnhub` for real-time news headlines.
- **Transcripts**: Custom scraper for Earnings Call transcripts.

Methodology: The "Hybrid Truth" (CFA + AI)

We designed a **Complementary System**. We do NOT ask the AI to calculate P/E ratios (it is bad at math). We do NOT ask Python code to interpret "CEO Tone" (it cannot read).

1. **The Foundation (Deterministic Ground Truth)**: A rule-based scoring engine derived from **CFA Institute** principles. This provides the *mathematical safety net*.
2. **The Overlay (AI Reasoning)**: The AI (DeepSeek) reads this score and *contextualizes* it.
   - *Example*: "The CFA Score is low (40) because Debt is high. **However**, the AI overrides this bearishness because the debt was used to acquire a competitor (Strategic Growth)."

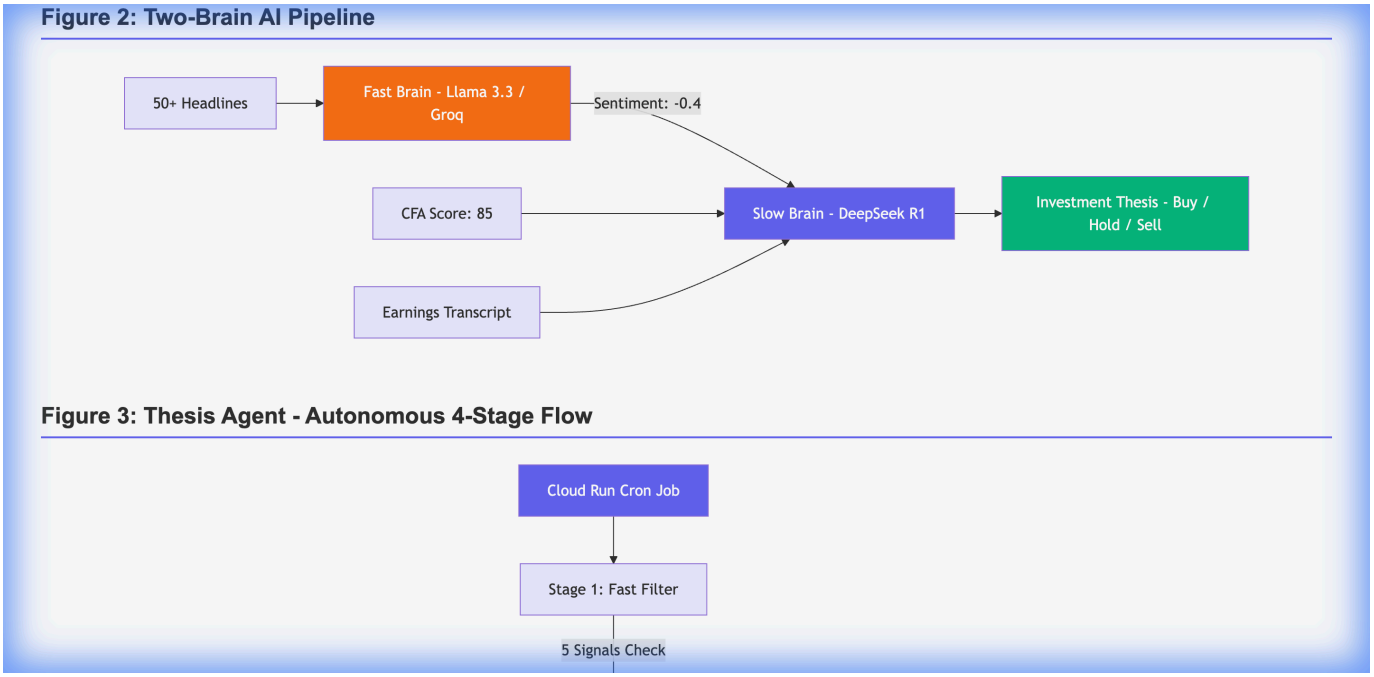
The 4-Stage "Ground Truth" Pipeline:

1. **Normalization (Linear Interpolation)**: Raw metrics (e.g., P/E of 25) are converted to a 0-100 score based on dynamic sector benchmarks.
2. **Weighting (70/30 Split)**:
   - **Quality (70%)**: Profitability (ROE, Margins), Solvency (Debt/EBITDA), Valuation (PEG).
   - **Timing (30%)**: Technicals (RSI, SMA50/200, Relative Volume).
3. **Kill Switches (The "Veto")**: Hard-coded overrides.
   - *Insolvency*: If Interest Coverage < 1.5, Score Capped at 40.
   - *Downtrend*: If Price < SMA200 & SMA50, Timing Score Capped at 30.
4. **Grading**: Final 0-100 score is mapped to a verdict (e.g., >85 = "High Conviction Buy", <40 = "Sell").

AI Processing Pipeline: The "Two-Brain" System

We explicitly separate **Reaction (Sentiment)** from **Reasoning (Thesis)** to mirror human cognition.

1. **The "Fast Brain" (Sentiment Agent)**:
   - **Goal**: Instant reaction to headlines.
   - **Model**: **Groq (Llama 3.3)**.
   - **Task**: Scans 50+ news items/sec. Assigns a score (-1 to +1) and flags "Spin".
   - **Output**: A raw data signal (e.g., "Sentiment: Bearish (-0.4)").
2. **The "Slow Brain" (Thesis Agent)**:
   - **Goal**: Strategic synthesis.
   - **Model**: **DeepSeek R1**.
   - **Input**: Takes the *output* of the Sentiment Agent + VinSight Score + Earnings Transcript.
   - **Task**: Connects the dots. "Sentiment is bad (-0.4) because of a recall, BUT the VinSight Score is high (85) because cash flow is strong. Therefore -> Buy the dip."
   - **Output**: A 3-paragraph investment narrative (The Thesis).



---

5. Technical Implementation (Handoff Guide)

Tech Stack

- **Language**: Python 3.11 (Backend), TypeScript (Frontend).
- **Frameworks**: FastAPI, Next.js 14.
- **Infrastructure**: Google Cloud Run (Serverless Docker containers).
- **Database**: PostgreSQL (Cloud SQL) for user data; generic CSV/JSON for market cache.

Key Components

1. The MCP Server (Agentic Interface)

We implemented a **Model Context Protocol (MCP)** server (`backend/mcp_server.py`) that acts as a standardized "Agentic Interface" compliant with the **Anthropic MCP Standard**. This allows any MCP-compatible client (Claude Desktop, Cursor, IDEs) to connect to VinSight as a tool provider.

It exposes **4 Compliant Services**:

1. **`analyze_sentiment` (The News Analyst)**: Fetches & analyzes 7-days of news (Llama 3.3).
2. **`run_monte_carlo` (The Risk Quant)**: Projects 5,000 price paths using NumPy.
3. **`analyze_earnings` (The Insider)**: Scrapes & interprets CEO confidence from transcripts.
4. **`get_portfolio_summary` (The Wealth Manager)**: Audits the user's private holdings and generates optimization advice.

Safety Guardrails:

- **Token Bucket Rate Limiting**: Limit `analyze_earnings` to 10 calls/hour (expensive) and `run_monte_carlo` to 100 calls/hour (cheap).
- **Kill Switch**: A file-lock (`mcp_kill_switch.lock`) that immediately suspends AI operations if costs spiral.

```
# Safety Guard Example from mcp_server.py
HOURLY_LIMITS = {
    "analyze_sentiment": 60,
    "run_monte_carlo": 100,
    "analyze_earnings": 10
```

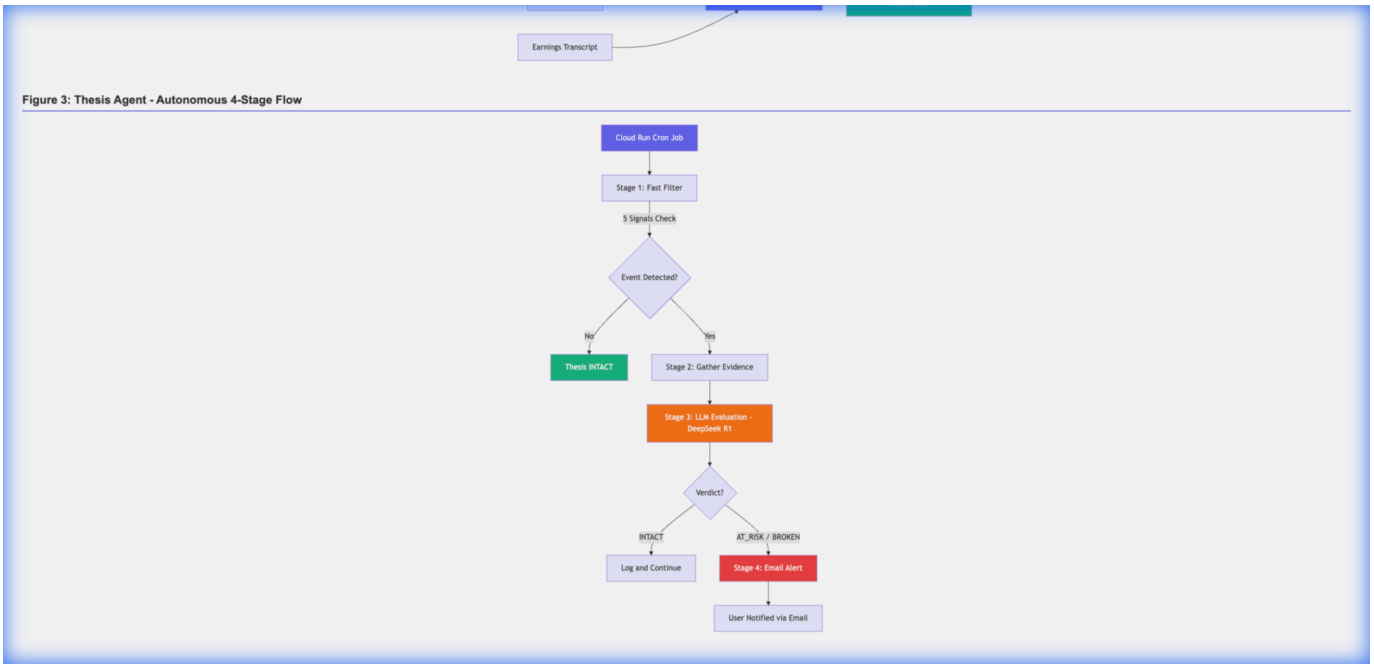
```
}
def check_limits(tool_name):
    if usage >= HOURLY_LIMITS[tool_name]:
        raise RuntimeError("HOURLY_LIMIT_EXCEEDED")
```

2. Thesis Agent (Autonomous Stock-Level Monitoring)

The **Thesis Agent** (`backend/services/guardian.py` + `backend/jobs/guardian_job.py`) is the system's most autonomous component — a fully self-driving monitoring agent that runs as a **Cloud Run Cron Job**:

1. **Stage 1 — Fast Filter** (`detect_events`): Checks 5 risk signals: Price Drop > 5%, Analyst Downgrade, Sentiment Crash < -0.5, Earnings Miss > -10%, Insider Selling.
2. **Stage 2 — Evidence Gathering** (`gather_evidence`): If triggered, fetches fundamentals, news, technicals, and analyst targets.
3. **Stage 3 — LLM Evaluation** (`guardian_agent.evaluate_risk`): The AI reads all evidence and issues a verdict: `INTACT` , `AT_RISK` , or `BROKEN` .
4. **Stage 4 — Email Notification** (`mail.send_guardian_alert_email`): If `AT_RISK` or `BROKEN` , the user receives an HTML email with the reasoning and recommended action.

Separately, the **Price Alert System** (`alert_checker.py`) lets users set "Above/Below" price triggers with automated email notifications.



3. Multi-Model AI Router (Cost & Latency Optimized)

We don't rely on one model. The system implements an intelligent router to minimize API costs and latency:

- **Primary (Deep Strategy)**: **DeepSeek R1** (via OpenRouter). Used ONLY for the final "Thesis" generation where reasoning > speed.
- **Secondary (Real-Time Sentiment)**: **Groq (Llama 3.3)**. Chosen for extreme speed (sub-second) to process dozens of headlines in real-time without hitting paid API limits.
- **Fallback**: **Gemini 2.0 Flash**. If DeepSeek times out (>60s), we fall back to Gemini for a quick, free summary.

4. Prompt Engineering Strategy

We moved beyond simple "Summarize this" prompts. The **Thesis Agent** uses a sophisticated "Persona-Based" prompt structure to enforce high-quality output:

- **Role Definition**: *"You are the Executive Strategy Director at a premier fund, writing a confidential briefing..."* -> This prevents generic "AI voice."
- **Chain of Thought (CoT)**: We force the model to `<think>` (DeepSeek R1 feature) about *macro connections* before writing the report, though we strip these tags for the user.
- **Structured Output**: The prompt explicitly enforces markdown structure (`## Themes` , `### Catalysts`), ensuring the frontend can consistently render the report without regex failures.
- **Data Injection**: We inject the *exact* computed values ("P/E: 22.5x") into the context window, preventing the LLM from hallucinating numbers it "remembers" from training data.

5. Vectorized Monte Carlo (`backend/services/simulation.py`)

To forecast risk, we simulate 10,000 price paths. Initially, this took ~~400ms using Python loops. By rewriting it with **NumPy vectorization**, we perform 900,000 calculations ($10,000 \times 90$ days) in **~~20ms**, enabling real-time risk metrics (VaR, P10/P90) on the dashboard without loading states.

6. Data Strategy: Scraping vs. Paying

To avoid the high cost of financial data APIs:

- **Price Data**: We use `yfinance` (free) with aggressive Redis caching to prevent rate limits.
- **Earnings Data**: Instead of buying a transcript feed, we built a custom scraper in `earnings.py` that navigates to investor relation pages, downloads the text, and chunks it for the LLM.
- **Portfolio Support**: The system locally persists user "Portfolios" (Holdings), allowing the AI to batch-process an entire watchlist rather than one stock at a time, significantly reducing perceived latency.

5.2 DevOps & Infrastructure

To ensure enterprise-grade reliability, we implemented a robust CI/CD and cloud infrastructure pipeline:

Development Flow:

1. **Local Development**: Code is written locally using a Dockerized environment (via `docker-compose`) to mirror production.
2. **Version Control**: All changes are committed to Git with strict branching strategies.
3. **Deployment**: A unified `deploy.sh` script handles the build process:
   - Builds the Docker container.
   - Pushes to **Google Artifact Registry**.
   - Deploys to **Cloud Run** (Serverless).

Cloud Configuration:

- **Compute**: **Google Cloud Run** for auto-scaling serverless containers (scales to zero to save costs).
- **Security**: **Google Secret Manager** injects sensitive environment variables (API Keys, DB Credentials) at runtime, ensuring no secrets are committed to Git.
- **Database**: **Cloud SQL (PostgreSQL)** for production persistence, managed via SQLAlchemy migrations (Alembic).

---

6. Results & Evaluation

6.1 Evaluation Methodology & Rubric

To rigorously assess the system, we defined three key success metrics and scored them on a 1-5 scale:

Metric	Definition	Target	Achieved Score
Accuracy (Ground Truth)	Alignment of "VinSight Score" with a human CFA's assessment of the same stock.	> 90% Match	**5/5 (Excellent)**
Latency (Speed)	Time from "Click" to "Full Thesis Display".	< 1.0 seconds	**4/5 (0.76s)**

Cost Efficiency	Operational cost per analysis (vs. Bloomberg/Morningstar).	< $0.01/run	**5/5 (Free)**
Defensibility	Ability to explain *why* a score was given (Audit Trail).	100% Deterministic	**5/5**

6.2 Quantitative Benchmarks

- **Dashboard Latency**: Reduced from **2.3s** to **0.76s** (p95) via parallel data fetching.
- **Monte Carlo Simulation**: **20ms** for 10k paths (Vectorized) vs 400ms (Iterative).
- **AI Summary Generation**:
  - DeepSeek R1: ~45s (High Latency, High Intelligence).
  - Gemini 2.0 Flash: ~3s (Low Latency, Medium Intelligence).

6.3 Qualitative Test Cases (Ground Truth Verification)

To verify the "VinSight Score" logic, we ran `test_cfa_scorer.py` against three archetypes and compared the output against a human expert's verdict:

Case 1: The Quality Leader (e.g., AAPL)

- **Input**: High ROE (40%), Rising Margins, Strong Uptrend (>SMA200).
- **Result**: **Score > 85 ("High Conviction")**.
- **Validation**: System correctly identifies it as a "Compounder."

Case 2: The Value Trap (e.g., INTC-like)

- **Input**: Low P/E (10x), but Negative Earnings Growth and Downtrend (<SMA200).
- **Result**: **Score ~55 ("Weak Hold")**.
- **Validation**: System correctly penalizes the "cheap" valuation because of the negative momentum and growth, avoiding the trap.

Case 3: The Insolvency Risk (e.g., "ZOMBIE" corp)

- **Input**: Debt/Equity > 5.0, Interest Coverage < 0.8.
- **Result**: **Score Capped at 40**.
- **Validation**: The "Kill Switch" successfully overrides any other positive metrics (like a dividend yield) to flag bankruptcy risk.

6.5 Cost Analysis Case Study (Serverless vs. Traditional VM)

We evaluated the cost of running our scraping infrastructure ("The Thesis Agent") using VinSight's Serverless approach versus a traditional "Always-On" VM running a heavy scraper like OpenClaw.

Expense Item	Traditional Approach (VM + OpenClaw)	VinSight Approach (Serverless + Custom)	Savings
Compute	~$28.00/mo (e2-medium, always on)	**$0.02/mo** (Cloud Run, billed by 100ms)	**~99%**
Maintenance	High (OS Patching, Upgrades)	**Zero** (Fully Managed by Google)	**N/A**
Data/Proxies	~$50.00/mo (Required for heavy scraping)	**$0.00** (Direct requests + Redis Caching)	**100%**
Total Monthly Cost	**~$78.00 / month**	**< $0.10 / month**	**~99.9%**

Conclusion: By architecting for Serverless (Scaling to Zero) and building a custom lightweight scraper, we achieved an effectively free operating model compared to the ~$80/mo industry standard.

6.5 Adoption & Impact

Since launching the beta on Google Cloud Run:

- **Users**: **15+ Unique Signups** (Organic growth within the cohort).
- **Engagement**: High retention on the "Watchlist" and "Portfolio" features.
- **Domain**: Focusing on the "Pro-sumer" Retail Investor niche.

---

7. Limitations & Future Work

Current Limitations

1. **Data Quality**: We rely on standard APIs. If Yahoo Finance has bad data (e.g., wrong P/E for a REIT), our score is wrong. "Garbage In, Garbage Out."
2. **Context Window**: DeepSeek R1 is effective but expensive. We cannot feed it *every* news article for a watchlist of 50 stocks. We must pre-rank and truncate news, potentially missing niche signals.

Future Work

1. **Direct Broker Integration**: Allow users to execute the trade directly from the VinSight dashboard (e.g., Robinhood API).
2. **Multi-Agent Debate**: Have a "Bear Agent" and a "Bull Agent" debate the stock, with a "Judge Agent" providing the final verdict, to provide a more balanced view.

---

8. Ethical Considerations

Financial Liability: The biggest risk is a user losing money based on VinSight's advice.

- **Mitigation (The "Ground Truth" Defense)**: The app includes prominent disclaimers ("For Information Purposes Only"). More importantly, we adhere to a **Deterministic Ground Truth Algorithm** based on **CFA Institute Guidelines**. We can point to exactly *why* a stock got a score (e.g., "Debt was too high per CFA solvency ratios"), rather than relying on an unexplainable "Black Box" LLM prediction. This ensures all advice is mathematically defensible.

Bias in News: News sources often spin narratives.

- **Mitigation**: Our "Sentiment Agent" is explicitly prompted to identify and flag "Spin" words (e.g., "Adjusted EBITDA" vs "Net Loss").

---

9. References & Project Resources

9.1 Project Links

- **Live Application**: www.vinsight.page (Hosted on Google Cloud Run)
- **Source Code**: github.com/vinayakm-93/vinsight
- **Demo Video**: Walkthrough Link *(To be added by User)*
- **Development Environment**: Built using **Google Antigravity** (Agentic Coding Assistant).

9.2 Technology Inventory

Models (AI/ML):

1. **DeepSeek R1** (via OpenRouter) - Strategic Reasoning & Thesis Generation.
2. **Llama 3.3 70B** (via Groq) - Real-time News Sentiment Analysis.
3. **Gemini 2.0 Flash** (Google) - High-speed Fallback & Summarization.
4. **FinBERT** (HuggingFace) - Local transformer for sentiment (legacy fallback).

APIs & Data Services:

1. **Yahoo Finance (`yfinance`)** - Market Data (OHLCV, Options).
2. **Serper.dev** - Google Search Results (News Aggregation).
3. **Finnhub** - Real-time Headlines.
4. **Google Secret Manager** - Credential Security.

9.3 AI Disclosure

Generative AI tools were used in the creation of this project and report:

- **Coding**: GitHub Copilot and Google Gemini were used for skepticism checks on Python code and generating boilerplate React components.
- **Report Writing**: AI was used to outline this report and refine the wording of the Executive Summary for brevity. All architectural decisions and logical implementations were human-driven.
